1 Preface

The Unified Material Model Driver for Plasticity (UMMDp) library is distributed as Fortran source codes. The Fortran compiler specified by the software vender in your analysis environment must be prepared. Please see the Abaqus manual for details of the environment required for compiling user subroutines.

In this guide, the sections of Abaqus' manual related to the use of the UMMDp are described below, as well as the details on how to use the UMMDp with Abaqus. In the following procedures, the prompts "%" and ">" represent the examples in UNIX/Linux and Windows, respectively. The common steps for using the UMMDp with Abaqus are:

- 1. Preparation of the UMMDp source files
 - Merge the UMMDp source files into one file.
- 2. Writing procedure to call tye UMMDp in the input data
 - To call the material user subroutine, specific keywords are required to be written in the input data. The keywords include the material constants, such as the coefficients of the yield criterion.
- 3. Execution of Abaqus with the UMMDp
 - When a command is typed to execute Abaqus, options are added to compile the UM-MDp and to link it to Abaqus.

2 Related Sections of Abaqus User's Manual

- 1. Command to execute with user-subroutine
 - Abaqus Analysis User's Guide
 - o 3.2.2 Abaqus/Standard, Abaqus/Explicit, and Abaqus/CFD execution.
- 2. Option for execution without compile
 - Abaqus Analysis User's Guide
 - o 3.2.18 Making user-defined executables and subroutines.
- 3. Keywords for setup of the UMMDp
 - Abagus Keywords Reference Guide
 - *DEPVAR: define the number of solution-dependent state variables.
 - *ORIENTATION: define local material axis for anisotropy.
 - *USER MATERIAL: define the material constants used in UMAT.
 - $\circ\,$ *USER OUTPUT VARIABLE: define the number of user output variables.
- 4. Specification of Abaqus user subroutines used in the UMMDp
 - Abaqus User Subroutines Reference Guide
 - o 1.1.44 UMAT: user subroutine to define a material's mechanical behavior.
 - 1.1.58 UVARM: user subroutine to generate element output.
- 5. User defined mechanical properties with UMAT
 - Abaqus Analysis User's Guide
 - o 26.7.1 User-defined mechanical material behavior.

3 Setup

3.1 Source Files

Concatenate the UMMDp source files into one single file with the plug-in file first. Simply use the batch files (.sh/.bat) or run each command separately.

• Unix/Linux

```
% cd dir_ummdp
% cp plug_ummdp_abaqus.f jobname_ummdp.f
% cat ummdp*.f >> jobname_ummdp.f
```

• Windows

```
> cd dir_ummdp
> copy plug_ummdp_abaqus.f jobname_ummdp.f
> type ummdp*.f >> jobname_ummdp.f
```

3.2 Abaqus Input File

This section describes the keywords in the input data file for use in the UMMDp.

1. Definition of the principal axis for the material anisotropy (refer to the manual)

```
*ORIENTATION, NAME=ORI-1
1., 0., 0., 1., 0.
3, 0.
```

2. Definition of the material model (the details will be provided later)

```
*MATERIAL, NAME=UMMDp

*USER MATERIAL, CONSTANTS=27

0, 0, 1000.0, 0.3, 2, -0.069, 0.936, 0.079,

1.003, 0.524, 1.363, 0.954, 1.023, 1.069, 0.981, 0.476,

0.575, 0.866, 1.145, -0.079, 1.404, 1.051, 1.147, 8.0,

0, 1.0, 0
```

Note that each line accedpts a maximum of 8 constants.

3. Define the number of internal state variables (SDV)

Set the number of state variables to 1+NTENS, where NTENS is the number of components of the tensor variables. NTENS=3 for plane stress or a shell element, and NTENS=6 for a solid element. The 1st "1" is reserved for the equivalent plastic strain, and NTENS is reserved for the plastic strain components. The following example corresponds to a solid element without kinematic hardening:

*DEPVAR

7,

In the case of kinematic hardening, the number of internal state variables corresponds to the equivalent plastic strain, plastic strain components and components of each partial back-stress tensor.

4. Define the user output variables (UVAR)

The UMMDp can output some user output variables. The request for user output variables is not mandatory, except when an uncoupled rupture criterion is used. If user output variables are requested, the following variables are output in the presented order:

- UVAR(1): equivalent stress computed through the yield criteria
- UVAR(2): flow stress computed through the isotropic hardening law
- UVAR(3:2+NTENS): total back-stress tensor components (when using a kinematic hard-ening law)
- UVAR(3+NTENS:end): rupture criterion parameter and variables (when using a kinematic hardening law)
- UVAR(3:2+NTENS): rupture criterion parameter and variables (when not using a kinematic hardening law)

*USER OUTPUT VARIABLES
8,

5. Define output variables for post processing

This keyword controls the output variables (e.g., equivalent plastic strain and equivalent stress) for post processing.

*OUTPUT, FIELD

*ELEMENT OUTPUT

LE, S, SDV, UVARM

3.3 Program Execution

To execute the program there are two options: (a) link the user subroutine in source code and (b) link the user subroutine previously compiled.

(a) To execute the program with the user subroutine in source code, execute the command:

%> abaqus job=jobname user=jobname_ummdp.f

(b)	To ex	xecute	the	program	with	the	user	subroutine	previously	compiled,	execute	the	com-
	mano	ds:											

- > abaqus job=jobname user=jobname_ummdp.obj
- % abaqus job=jobname user=jobname_ummdp.o

The command that compiles the file jobname_ummdp.obj/o is:

%> abaqus make library=jobname_ummdp.f

4 Input

The input data in UMMDp is defined as follows:

- 1. Parameter for Debug and Print
- 2. Parameters for Elastic Properties
- 3. Parameters for Yield Criterion
- 4. Parameters for Isotropic Hardening Law
- 5. Parameters for Kinematic Hardening Law

The detail of data is shown as follows and in addition, an example of input data is described.

4.1 Debug and Print

The first input parameter corresponds to the definition of debug and print mode, defined by the variable nvbs0. The option selected here will have an effect on the .dat file from Abaqus execution. It is a mandatory parameter and the options are:

- 0 Error messages only
- 1 Summary of Multistage Return Mapping
- 2 Detail of Multistage Return Mapping and summary of Newton-Raphson
- 3 Detail of Newton-Raphson
- 4 Input/Output
- 5 All status for debug and print

4.2 Elastic Properties

- prela(1) ID for elastic properties
- prela(2~) Data depends on ID

Only isotropic Hooke elastic properties can be defined. There are 2 ways to set them:

- Young's Modulus and Poisson's Ratio ✓
 - ID: 0
 - Parameters: 2
 - \circ prela(1) = 0
 - \circ prela(2) = 200.0E+3 (Young's modulus E)
 - \circ prela(3) = 0.3 (Poisson's ratio ν)

- \blacksquare Bulk Modulus and Modulus of Rigidity \checkmark
 - ID: 1
 - Parameters: 2
 - o prela(1) = 1
 - o prela(2) = 166666.7 (Bulk modulus $K = E(1 2\nu)/3$))
 - prela(3) = 76923.08 (Modulus of rigidity $G = E(1 + \nu)/2$)

4.3 Yield Criteria

• pryld(1) - ID for yield function

(Negative values specify plane stress yield criteria)

• pryld(2~) - Data depends on ID

Identification number for yield criteria and required parameters are introduced. Please refer to the original papers for more detail on the formulation and meaning of parameters.

- von Mises ✓
 - □ von Mises, R., 1913. Mechanik der festen Korper im plastisch deformablen Zustand. Gottin Nachr Math Phys, 1:582–592.
 - ID: 0
 - \circ pryld(1) = 0
- Hill 1948 ✓
 - $\hfill\square$ Hill, R., 1949. The theory of plane plastic strain for anisotropic metals. Proc Royal Soc Lond Ser Math Phys Sci 198, 428–437.
 - ID: 1
 - Parameters: 6
 - \circ pryld(1) = 1
 - o pryld(1+1) = F
 - o pryld(1+2) = G
 - o pryld(1+3) = H
 - \circ pryld(1+4) = L
 - o pryld(1+5) = M
 - o pryld(1+6) = N
 - \Box The parameters are the same as Hill's original paper. When F=G=H=1 and L=M=N=3, Hill's function is identical to von Mises.

4.5 Kinematic Hardening Laws

- prkin(1) ID for kinematic hardening
- prkin(2~) Data depends on ID

The equation of backstress is introduced for each law, where $\dot{\alpha}$ is the increment of the total backstress tensor, $\dot{\alpha}_i$ is the increment of the partial backstress tensor, α is the total backstress tensor, $\dot{\alpha}_i$ is the partial backstress tensor, $\dot{\varepsilon}^p$ is the increment of plastic strain tensor, and \dot{p} is the increment of equivalent plastic strain. Depending on the law, a specific number of additional state variables (SDV) and user output variables (UVAR) are required. The variable k represents the number of tensor components (NTENS).

- \blacksquare No Kinematic Hardening \checkmark

 - \circ prkin(1+4) = k
 - \circ prkin(1+5) = b

4.6 Uncoupled Rupture Criteria

- prrup(1) ID for uncoupled rupture criterion
- prrup(2) Flag to complete (0) or terminate (1) analysis if critical value is reached
- prrup(3~) Data depends on ID

The equation of the uncoupled rupture criterion is introduced for each criterion, where W is the rupture parameter, σ_1 is the maximum principal stress, σ_h is the hydrostatic stress, $\bar{\sigma}$ is the equivalent stress, \dot{p} the equivalent plastic strain rate, and W_L the user-defined critical value. Depending on the criterion, a specific number of additional user output variables (UVAR) are required.

- \bullet No Uncoupled Rupture Criterion $\ensuremath{\checkmark}$
 - ID: 0
 - \circ prrup(1) = 0

- Equivalent Plastic Strain: $W = \int_0^{\varepsilon_{\rm f}} \dot{p} \, \mathrm{d}t$ ✓
 - ID: 1
 - Parameters: 1
 - \bullet User Output Variables: +2
 - o prrup(1) = 1
 - \circ prrup(1+2) = $W_{\rm L}$
 - □ UVAR(_+1) = equivalent plastic strain
 - □ UVAR(_+2) = rupture parameter normalised by critical value

```
\blacksquare Forming Limit Diagram: W = \frac{\varepsilon_1}{\varepsilon_1^{\text{FLD}}} \checkmark
```

```
• ID: 6
```

• Parameters: 1

 \bullet User Output Variables: + 5

```
o prrup(1) = 6
o prrup(1+2) = W<sub>L</sub>

UVAR(_+1) = maximum principal strain
UVAR(_+2) = minimum principal strain
UVAR(_+3) = projection of maximum principal strain on FLD
UVAR(_+4) = rupture parameter
UVAR(_+5) = rupture parameter normalised by critical value
```

• Additionaly, this rupture criterion requires the definition of data points, representative of the forming limit curve major and minor strains. The following lines should be added to the input file below the material definition, where in red are indicated the fields to be modified. Do not change anything else. The number of properties should be modified according to the number of data points. Below *PROPERTY TABLE, TYPE=FLD1 insert the major strain data points, and below *PROPERTY TABLE, TYPE=FLD2 insert the minor strain data points. Please note that each line only accepts a maximum of 8 properties, while multiple lines are accepted.

```
*PROPERTY TABLE TYPE, NAME=FLD1, PROPERTIES=5

*PROPERTY TABLE TYPE, NAME=FLD2, PROPERTIES=5

*TABLE COLLECTION, NAME=FLD

*PROPERTY TABLE, TYPE=FLD1

0.3, 0.2, 0.1, 0.2, 0.3

*PROPERTY TABLE, TYPE=FLD2

-0.2, -0.1, 0.0, 0.1, 0.2
```

5 Example

• Debug and Print: Error messages only

• Elastic Properties: $E{=}200$ GPa, $\nu{=}0.3$

• Yield Criterion: Yld2000-2d

• Isotropic Hardening Law: Voce + Linear

• Kinematic Hardening Law: Chaboche (1979) - Ziegler Type

• Uncoupled Rupture Criterion: Cockroft and Latham

The material parameters and IDs are given as input to the UMMDp in one dimensional array, named by default props in the program. In the beginning of the UMMDp, this array is copied to a new variable prop, and the variable to define debug and print mode is excluded from this new array.

0	props(1)	=	0	Debug and Print ID
0	props(2)	=	0	Elastic Property ID
0	props(3)	=	200000.0	E
0	props(4)	=	0.3	ν

                                             W_{\rm L}
```

This prop(i) array is divided in the UMMDp as follow:

- prela(i) Elastic Properties
- pryld(i) Yield Criterion
- prihd(i) Isotropic Hardening Law
- prkin(i) Kinematic Hardening Law
- prrup(i) Uncoupled Rupture Criterion

The model ID is stored in the top of each of these arrays. Here, it is shown some parts of a plane stress example for the Abaqus input file. The red letter indicates ID of each properties.
